### Experiment No. 12

**Title:** Naïve String matching.

**Aim:** To study and implement Naïve string matching Algorithm

**Objective:** To introduce String matching methods

**Theory:**

The naïve approach tests all the possible placement of Pattern P [1.....m] relative to text T [1.....n]. We try shift  $s = 0, 1, \dots, n-m$ , successively and for each shift  $s$ . Compare T [s+1.....s+m] to P [1 ..... m].

The naïve algorithm finds all valid shifts using a loop that checks the condition  $P [1.....m] = T [s+1 ..... s+m]$  for each of the  $n - m + 1$  possible value of  $s$ .

**Example:**

Text : A A B A A C A A D A A B A A B A

Pattern : A A B A

A	A	B	A							A	A	B	A		
A	A	B	A	A	C	A	A	D	A	A	B	A	A	B	A
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
												A	A	B	A

Pattern Found at 0, 9 and 12

**Algorithm:**

### THE NAIVE ALGORITHM

The naive algorithm finds all valid shifts using a loop that checks

the condition  $P[1\dots m] = T[s+1\dots s+m]$  for each of the  $n-m+1$

possible values of  $s$ . ( $P$ =pattern,  $T$ =text/string,  $s$ =shift)

**NAIVE-STRING-MATCHER( $T, P$ )**

- 1)  $n = T.length$
- 2)  $m = P.length$
- 3) **for**  $s=0$  to  $n-m$
- 4)     **if**  $P[1\dots m] == T[s+1\dots s+m]$
- 5)         **printf** "Pattern occurs with shift "  $s$

**Implementation:**

```
#include <stdio.h>
#include <string.h>
int match(char [], char []);
int main() {
    char a[100], b[100];
    int position;
    printf("Enter some text\n");
    gets(a);
    printf("Enter a string to find\n");
    gets(b);
```

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

---

```
position = match(a, b);
if (position != -1) {
    printf("Found at location: %d\n", position + 1);
}
else {
    printf("Not found.\n");
}
return 0;
}

int match(char text[], char pattern[]) {
    int c, d, e, text_length, pattern_length, position = -1;
    text_length = strlen(text);
    pattern_length = strlen(pattern);

    if (pattern_length > text_length) {
        return -1;
    }
    for (c = 0; c <= text_length - pattern_length; c++) {
        position = e = c;
        for (d = 0; d < pattern_length; d++) {
            if (pattern[d] == text[e]) {
                e++;
            }
            else {
                break;
            }
        }
        if (d == pattern_length) {
```

# Vidyavardhini's College of Engineering and Technology

## Department of Artificial Intelligence & Data Science

---

```
    return position;  
}  
}  
return -1;  
}
```

### Output:

```
Enter some text  
aabbccddaabbdhgaaabbcc  
Enter a string to find  
aabbcc  
Found at location: 1  
  
=== Code Execution Successful ===|
```

**Conclusion:** Experiment underscores the utility of the naive string matching algorithm in efficiently locating occurrences of a pattern within a text. While straightforward in approach, its effectiveness in basic string searching tasks highlights its foundational significance in algorithmic design and serves as a benchmark for more complex pattern matching algorithms.
